Methods that evaluate Hessians (or approximate Hessians, using finite differences): Newton's method; Sequential quadratic programming: A Newton-based method for small-medium scale constrained problems. Some versions can handle large-dimensional problems. Interior point methods: This is a large class of methods for constrained optimization. Some interior-point methods use only (sub)gradient information and others of which require the evaluation of Hessians.

*Mathematical optimization - Wikipedia*  
Monte Carlo methods, or Monte Carlo experiments, are a broad class of computational algorithms that rely on repeated random sampling to obtain numerical results. The underlying concept is to use randomness to solve problems that might be deterministic in principle. They are often used in physical and mathematical problems and are most useful when it is difficult or impossible to use other ...
